

COVID-19

Imaging findings

R.JAVADRASHID M.D.

- 
- ▶ Infection by SARS-CoV-2 virus ranges from asymptomatic to severe and sometimes fatal disease, most frequently the result of acute lung injury.
 - ▶ The role of imaging has evolved during the pandemic, initially with CT as alternative and possibly superior test compared to RT-PCR, to a more limited role based on specific indications.
 - ▶ Furthermore, some studies looking at the extent of lung involvement on chest radiography and CT showed correlations with critical illness and need for mechanical ventilation.
 - ▶ In addition to pulmonary manifestations, cardiovascular complications such as thromboembolism and myocarditis have been ascribed to COVID-19, sometimes contributing to neurologic and abdominal manifestations

Indications for Imaging in COVID-19

- ▶ While some early proponents particularly in China advocated for routine imaging in diagnosis of suspected COVID-19 pneumonia, others particularly in the United States and Europe proposed a much more conservative approach
- ▶ Based on expert opinions of panel members, recommendations were issued including: **no indication for routine imaging as a screening test for COVID-19 in asymptomatic individuals, no indication for daily CXR in stable intubated patients with COVID-19, and CT is indicated in patients with functional impairment, hypoxemia, or both after recovery from infection.**

Chest radiograph

- ▶ Findings of COVID-19 on CXR vary, ranging from normal in the early stages of disease to unilateral or bilateral lung opacities, sometimes with a basilar and strikingly peripheral distribution
- ▶ underlying comorbidities such as chronic lung disease or congestive heart failure may confound CXR interpretation

- ▶ Chest-films can be useful in the follow-up of the disease

At admission

4 hours

24 hours

48 hours

72 hours

Possible role of CT

- ▶ CT can play a role in:
- ▶ Triage of patients:
 - no COVID-19
 - possible or most likely COVID-19
 - severity of the disease
- ▶ Prediction of worsening
- ▶ Prediction of improvement
- ▶ Problem solver

CHEST CT

- ▶ **Ground glass**

- ▶ Ground glass (GGO) pattern is the most common finding in COVID-19 infections.

They are usually multifocal, bilateral and peripheral, but in the early phase of the disease the GGO may present as a unifocal lesion, most commonly located in the inferior lobe of the right lung

Crazy paving

- ▶ Sometimes there are thickened interlobular and intralobular lines in combination with a ground glass pattern. This is called crazy paving.
- ▶ It is believed that this pattern is seen in a somewhat later stage

Vascular dilatation

- ▶ A typical finding in the area of ground glass is widening of the vessels (arrow).

Reverse halo sign

Subpleural bands and Architectural distortion

- ▶ In some case there is architectural distortion with the formation of subpleural bands.

consolidation

Traction Bronchiectasis

- ▶ Another common finding in the areas of ground glass is traction bronchiectasis (arrows).

- ▶ Consolidation superimposed on GGO as the initial imaging presentation is found in a smaller number of cases, mainly in the elderly population.
- ▶ Septal thickening, bronchiectasis, pleural thickening, and subpleural involvement are some of the less common findings, mainly in the later stages of the disease.
- ▶ Pleural effusion, pericardial effusion, lymphadenopathy, cavitation, CT halo sign, and pneumothorax are some of the uncommon but possible findings seen with disease progression

intitial CT-patterns in COVID-19

Ground-glass opacification	88%
Bilateral involvement	88%
Posterior distribution	80%
Multilobar involvement	79%
Peripheral distribution	76%
Consolidation	32%

CT-changes over time

Early stage	0-4 days	GGO, partial crazy paving, lower number of involved lobes
Progressive stage	5-8 days	Progressive (5-8 days): Extension of GGO, increased crazy paving pattern
Peak stage	10-13 days	Consolidation
Absorption stage	≥14 days	Gradual resolution

Advanced-phase disease is associated with a significantly increased frequency of:

- ▶ GGO plus a reticular pattern (crazy paving)
- ▶ Vacuolar sign
- ▶ Fibrotic streaks
- ▶ Air bronchogram
- ▶ Bronchus distortion
- ▶ Subpleural line or a subpleural transparent line
- ▶ Pleural effusion

Radiological Society of North America Expert Consensus Statement on Reporting Chest CT Findings Related to COVID-19.

Proposed Reporting Language for CT Findings Related to COVID-19

Routine screening CT for diagnosis or exclusion of COVID-19 is currently not recommended by most professional organizations or the US Centers for Disease Control and Prevention

COVID-19 pneumonia imaging classification	Rationale (6-11)	CT Findings ⁺	Suggested Reporting Language
Typical appearance	Commonly reported imaging features of greater specificity for COVID-19 pneumonia.	<p>Peripheral, bilateral , GGO* with or without consolidation or visible intralobular lines (“crazy-paving”)</p> <p>Multifocal GGO of rounded morphology with or without consolidation or visible intralobular lines (“crazy-paving”)</p> <p>Reverse halo sign or other findings of organizing pneumonia (seen later in the disease)</p>	“Commonly reported imaging features of (COVID-19) pneumonia are present. Other processes such as influenza pneumonia and organizing pneumonia, as can be seen with drug toxicity and connective tissue disease, can cause a similar imaging pattern.” [Cov19Typ]^

Typical CT imaging features for COVID-19. Unenhanced, thin-section axial images of the lungs in a 52-year-old man with a positive RT-PCR (A-D) show bilateral, multifocal rounded (asterisks) and peripheral GGO (arrows) with superimposed interlobular septal thickening and visible intralobular lines (“crazy-paving”)

Typical CT imaging features for COVID-19. Unenhanced, thin-section axial (A-C) and coronal multiplanar reformatted (MPR) images (D) of the lungs in a 77-year-old man with a positive RT-PCR show bilateral, multifocal rounded and peripheral GGO.

- Typical CT imaging features for COVID-19. Unenhanced axial (A-C) and sagittal MPR (D) images of the lungs in a 29-year-old man with a positive RT-PCR show multiple bilateral, rounded consolidations with surrounding GGO.

COVID-19

COVID-19

Organizing pneumonia

Influenza A pneumonia

Indeterminate appearance	Nonspecific imaging features of COVID-19 pneumonia.	<p>Absence of typical features AND</p> <p>Presence of:</p> <p>Multifocal, diffuse, perihilar, or unilateral GGO with or without consolidation lacking a specific distribution and are non-rounded or non-peripheral.</p> <p>Few very small GGO with a non-rounded and non-peripheral distribution</p>	<p>“Imaging features can be seen with (COVID-19) pneumonia, though are nonspecific and can occur with a variety of infectious and noninfectious processes.” [Cov19Ind]^</p>
---------------------------------	---	---	---

This finding is common in COVID-19 pneumonia but occurs in a wide variety of diseases such as acute hypersensitivity pneumonitis, Pneumocystis infection, and diffuse alveolar hemorrhage, which are difficult to distinguish by imaging alone.

COVID-19

Drug toxicity

Drug toxicity

A

Pneumocystis pneumonia

B

Atypical appearance	Uncommonly or not reported features of COVID-19 pneumonia.	Absence of typical or indeterminate features AND Presence of: Isolated lobar or segmental consolidation without GGO Discrete small nodules (centrilobular, “tree-in-bud”) Lung cavitation Smooth interlobular septal thickening with pleural effusion	“Imaging features are atypical or uncommonly reported for (COVID-19) pneumonia. Alternative diagnoses should be considered.” [Cov19Aty]^
----------------------------	--	--	--

Atypical features are those that are reported to **be uncommon or not occurring in COVID-19 pneumonia** and are more typical of other diseases such as lobar or segmental consolidation in the setting of a **bacterial pneumonia**, cavitation from necrotizing pneumonia, and tree-in-bud opacities with centrilobular nodules, as can occur with a variety of community acquired infections and aspiration

COVID-19 positive vs coexistent infection

Atypical CT imaging features for COVID-19. Contrast-enhanced axial CT image (A) and frontal chest radiograph (B) showing segmental consolidation without significant GGO. Although this patient tested positive for COVID-19, the imaging features are not typical and could represent pneumonia related to COVID-19 or a secondary infectious process.

Negative for pneumonia	No features of pneumonia	No CT features to suggest pneumonia.	“No CT findings present to indicate pneumonia. (Note: CT may be negative in the early stages of COVID-19.) [Cov19Neg]^
-------------------------------	--------------------------	--------------------------------------	---

Pros and Cons of Standardized Reporting for Chest CT Findings Related to COVID-19

Routine screening CT for diagnosis or exclusion of COVID-19 is currently not recommended by most professional organizations or the US Centers for Disease Control and Prevention

Pros	Cons
<ul style="list-style-type: none">• Clinicians may be unsuspecting of COVID-19 in atypical presentations• Initial RT-PCR may be negative, and typical features may encourage repeat confirmatory testing• Standardized reporting language can improve report quality and clarity by ensuring consistent terminology• Reporting data can be used for future teaching, research, clinical quality improvement, and future management pathways	<ul style="list-style-type: none">• The true sensitivity and specificity of chest CT are unknown. Even patients with a normal chest CT or only atypical features may have COVID-19• Clinicians may feel that having "COVID-19" in a report boxes them in and limits their options for patient management• Patients may be apprehensive about having terminology like "COVID-19" or "coronavirus" in their reports and medical records

CT involvement score

The severity of the lung involvement on the CT correlates with the severity of the disease.

- ▶ **Visual assessment**

The severity on CT can be estimated by visual assessment. This is the easiest way to score the severity.

- ▶ **Severity score**

Another method is by scoring the percentages of each of the five lobes that is involved:

- ▶ 1.< 5% involvement
- ▶ 2.5%-25% involvement
- ▶ 3.26%-49% involvement
- ▶ 4.50%-75% involvement
- ▶ 5.> 75% involvement.
- ▶ The total CT score is the sum of the individual lobar scores and can range from 0 (no involvement) to 25 (maximum involvement), when all the five lobes show more than 75% involvement.

CTA

- ▶ Thrombotic lesions affected COVID-19-involved lung in all cases with a lower thrombus burden and lower rate of proximal pulmonary artery involvement compared to controls
- ▶ Pulmonary emboli or thrombi were present in the segmental and more distal vessels in greater than 90% of patients

COVID-19 Differential Diagnosis

COVID-19 Ground glass mimickers

- Inadequate inspiration

- Mosaic attenuation

- hypoperfusion in pulmonary emboli
- bronchopathy with secondary vasoconstriction in:
 - asthma
 - bronchiolitis obliterans
 - hypersensitivity pneumonitis

Inadequate inspiration

Mosaic attenuation

Pulmonary cardiogenic edema

- ▶ ground-glass opacities are typically more centrally distributed with sparing of the peripheral parenchyma
- ▶ Accompanying signs suggestive of cardiogenic edema:
- ▶ Interlobular septal thickening
- ▶ Diffuse vascular enlargement
- ▶ Lymph node enlargement
- ▶ Structural cardiac pathology
- ▶ Pleural fluid
- ▶ Clinical presentation of the patient

Pulmonary infarctions

Alveolar hemorrhage

Eosinophilic pneumonia

- ▶ Clinical presentation with slow onset of symptoms
- ▶ Association with asthma
- ▶ Eosinophilia in bronchioalveolar lavage and blood samples
- ▶ Mainly upper lung zone distribution

Drug-induced pneumonitis

Hypersensitivity pneumonitis

- ▶ Centrilobular nodules
- ▶ "Headcheese sign" with a mixture of lobules with ground glass, normal density parenchyma, and air trapping
- ▶ Clinical presentation with a history of exposure to sometimes unknown antigens
- ▶ HP patients can develop fibrotic changes in a later stage.

Nonspecific interstitial pneumonia

- ▶ The opacities are not demarcated
- ▶ No confirmatory patterns of COVID-19
- ▶ Mostly stable over time
- ▶ Clinical presentation is distinct from infection.

Adenocarcinoma

- ▶ Multifocal adenocarcinoma can present as bilateral ground glass opacities,
- ▶ a more geographical and diffuse distribution.

Alveolar proteinosis

- ▶ Crazy paving in alveolar proteinosis is much more diffuse than in COVID-19, with incidental lobular or geographic sparing, and is frequently disproportional with severity of complaints.

Organizing pneumonia

- ▶ Patterns compatible with organizing pneumonia commonly occur in COVID-19.
- ▶ It is regarded as a confirmatory pattern, reflecting a later stage in the temporal evolution of the parenchymal abnormalities.

Influenza pneumonia

- ▶ Influenza virus infection can result in bilateral ground-glass opacities, consolidations and crazy paving that appear similar to COVID-19.
- ▶ Typical features of influenza are:
 - ▶ Mucoid airway impaction
 - ▶ Linear opacities
 - ▶ Central distribution

Pneumocystis pneumonia

- ▶ Pneumocystis pneumonia also causes bilateral ground-glass and in later stages consolidations with or without crazy paving.
- ▶ However, this frequently occurs in a more central distribution than in COVID-19, and only in immunocompromised patients.
- ▶ PCP is furthermore associated with pulmonary cysts and spontaneous pneumothoraces, although pneumothoraces and bullae also present in a small minority of hospitalized COVID-19 patients.

Adult respiratory distress syndrome

- ▶ Diffuse alveolar damage can also show peripheral ground-glass, consolidations and crazy paving, which can be similar to the alveolar damage in patients with COVID-19 (left), but also more gravity dependent reflecting permeability edema (right).
- ▶ ARDS can only occur in the appropriate setting, such as in a postoperative situation or in case of prolonged mechanical ventilation.

Table 3: Differential diagnosis of CT ground glass opacities in the COVID-19 era

Diagnosis	Association	Location of Parenchymal abnormality	Small nodules	Cavitation	Subpleural sparing	Lymphadenopathy	Pleural effusion	Other findings
COVID-19	Signs and symptoms of infection, loss of sense of taste or smell, leukopenia, lymphopenia	Bilateral, basal and subpleural predominant	-	-	-	-	-	
Pulmonary edema	History of heart disease	Perihilar	-	-	-	++	+	Imaging findings of heart disease - cardiomegaly, Coronary calcifications
Bacterial pneumonias	Signs and symptoms of infection	No specific	-	+	-	++	+	
Viral pneumonias	Signs and symptoms of infection; some patients may be immunosuppressed	No specific	-	-	-	+	+/-	No specific differentiating features
Aspiration	Dilated Esophagus Neuromuscular disorders Anatomical abnormality, e.g., tracheo-esophageal fistula, head and neck malignancy etc.	Dependent	Dependent centrilobular and Tree-in-bud ++	+/-	-	+/-	+/-	Air-way opacification
Pneumocystis carinii pneumonia	Immunosuppression CD4 <200	Upper	-	-	-	-	-	Cysts +/- Spontaneous pneumothorax possible
Nonspecific Interstitial pneumonitis	Connective tissue disorder or other predisposing condition	Subpleural Lower lung zone predominant Subpleural sparing	-	-	++	+/-	-	Features of fibrosis- traction bronchiectasis, architectural distortion Honeycombing +/-
Cryptogenic organizing pneumonia	Predisposing conditions +/-	Subpleural, peri-bronchovascular	-	-	-	-	-	Perilobular thickening Migratory opacities Prior episodes
Hypersensitivity pneumonitis	Exposure history in 70%	Upper lung zone predominant	Upper lung zone predominant centrilobular ground glass nodules	-	-	-	-	Air trapping on expiratory CT images Mosaic attenuation Upper and/or mid lung predominant fibrosis +/-
Drug induced toxicity	History of recent drug exposure	No zonal distribution	-	-	-	-	-	No specific differentiating imaging features
Desquamative interstitial pneumonia	Smoking history (in 90%)	Lower lung zone	-	-	-	-	-	Small cystic spaces +/-.
Diffuse alveolar hemorrhage	History of hemoptysis Renal disease Other systemic illness	No specific	-	-	-	-	-	H/o prior episodes may be present Migratory opacities
Pulmonary alveolar proteinosis	Tobacco use Subacute symptom onset H/o prior episodes	No specific	-	-	-	-	-	Pronounced crazy-paving pattern often with lobular or geographic sparing.
e-cigarette or vaping product use associated lung injury	History of vaping (New or increased use history may be helpful)	No specific	Centrilobular and upper lung zone predominant nodularity	-	++	-	-	Subpleural sparing
Chronic Eosinophilic Pneumonia	Asthma Subacute presentation	Upper lung zone	-	-	-	-	-	Crazy paving +/-
